PREFACE.

IN presenting to the public the result of his observations in relation to the weather, and of the more remarkable events transpiring in the Old Colony and vicinity, the author makes no pretence of introducing a work to be valued for its scientific discoveries, or its literary attainments; but he introduces, rather, the diary of a plain mechanic, surveyor, and farmer, kept for sixty-three years, with such completeness as his means of information would allow, and, as is generally believed, the most perfect *consecutive* record for so long a period of time. The facts here embraced are compiled in a convenient form for reference, and are given to the public at the earnest solicitation of a large number of his friends, who have deemed this record worthy to be preserved.

To meet the almost universally conceived opinions that the moon, in some way, is made to affect the weather, the position of that planet is given for the entire period; and though the "weather wise" who

look for frosts on the occasion of a full moon, or in any other way imagine that this "heavenly orb which revolves round the earth" has any effect upon the weather, may be disappointed to find their theories exploded, the *facts* will be no less valuable, either to the scholar or the man of business.

In the APPENDIX, the author has sought only to submit a few of the observations and opinions of scientific men—already before the public—to show that they are in harmony with his own record of what has actually transpired.

Presuming upon the indulgence of the public, and profoundly grateful to his numerous friends for their many words and acts of encouragement in the prosecution of his labors, this volume is now presented to the reader, in the hope that the result of his labor will not be unacceptable.

GALES IN 1869.

Since the great gale of 1815 there has been no tempest in New Englaud equal to that which occurred on September 8th, 1869. Though of short duration, hardly continuing more than an hour, the effects of the wind were terrible, whole forests, houses, churches, and vessels being prostrated, and the loss to property being counted in millions in Massachusetts alone. Bridges were carried away on the Old Colony, Cape Cod, and other Railroads, so as to render them impassable; church spires were blown down in North Bridgewater, Abington, Braintree, and numerous other places, and several lives were sacrificed to the storm. This gale was confined almost exclusively to Massachusetts, Rhode Island, New Hampshire, and Maine.

On October 4th, a storm of rain commenced at the south of New York, accompanied by a high wind, increasing as the storm progressed northward, doing immense damage to property through Massachusetts, New York, and Vermont, sweeping miles of railroad, and hundreds of bridges, in its course, and obstructing the regular lines of travel between New York and the East for several days. The Boston and Albany Railroad, which had been thirty years constructed, was carried away at Wilbraham, and other places, requiring weeks to rebuild it, while at Fitchburg, and other large manufacturing towns, the damage to property could hardly be estimated. This storm was very destructive along the entire line of the Hudson river.

EXPLANATION.

The changes of the moon on the preceding pages are represented by the following characters:

First Quarter. Full Moon. Last Quarter. New Moon.

EFFECT OF THE MOON UPON THE WEATHER.

Most of the north-east storms, north of Cape Hatteras, begin in the south-west, and move against the easterly wind about six or eight miles an hour, often continuing without much change for several days. But when the wind is S. E. or S., rains are generally short, lasting but a few hours. They rise in the West or North-west, and move towards the Atlantic, generally with sudden and heavy rains.

Thunder showers almost always form in the West, and move closely against S. or S. E. winds towards the ocean; but when they gather near us, they form from low clouds, and produce violent rains accompanied with thunder. Sometimes in a clear, hot morning scuds are seen rising and moving towards the sun during the forenoon, without much wind, stopping a little east of us, and increasing in size. Soon one or more of these clouds, white at first, becomes black on the farther side, and rain begins to fall, as we can see by the dark streaks nearly, or quite, perpendicular. Thunder is soon heard; the clouds grow larger and scarcely move; but their tendency is towards the ocean, and, while they continue, heavy showers, and, sometimes, violent tempests occur.

Some people suppose that thunder clouds will not come up against the moon when nearly, or quite, in the full; and if they do at all there is seldom much rain or thunder. In proof that this impression is incorrect, one of the severest tempests, accompanied with a great quantity of rain, took place in the afternoon of August 5th, 1803. The water in the Matfield river rose to an enormous height, reaching three feet above Joppa Bridge.

On August 2nd, 1819, about three days before the full of the moon, occurred one of the most violent tempests on record, attended by the most frequent claps of thunder which the writer has ever known in one day. Through the day clouds were passing north of us towards the East. About five o'clock in the afternoon a cloud gathering in the West came up against the E. wind, moving slowly, with terrible thunder and lightning—much of it very near us. Many trees were struck, several houses were damaged, six barns were destroyed by lightning within the town of Bridgewater, and some lives were lost. This shower lasted about an hour and a half. For thirty minutes the darkness was extreme. The venerable Deacon John Whitman, then eighty-four years old, told the writer that he had never before known anything of the kind equal to it.

In the night of July 25th, 1826, near the last quarter of the moon, there was much lightning, but little rain.

In 1837, July 25th, a great deal of thunder was heard in the night, and much damage was done by lightning. This was on the wane of the moon.

In 1850, July 25th, a tempest occurred in the night, and on the full of the moon. The thunder was heavy, and some damage done by lightning.

In July 4th, 1867, three days after the new moon, a heavy tempest occurred; considerable damage done by lightning—three cows killed in this town.

In the evening of July 3rd, 1868, one day before the full moon, there was a thunder shower a little north of us. Two days later, and one day after the full, a tempest occurred after the cloud had passed by us. Now, if the moon attracts the clouds, and draws them north or south of us, and showers and tempests take place on both sides after or about the same time, it is impossible for one cloud

to be attracted and the other driven off. No cloud can be seen when twenty-five miles off. The moon is the same there as here, and for hundreds of miles at the same time, with but a few minutes' variation.

When clouds are seen coming from any point, they appear to move in a circular course. We then notice two or more low clouds rising near each other and moving fast. When they pass by on both sides of us, they appear ten times as far apart, and after they have passed, come together as before, probably at the same distance all the way. We notice that a high cloud will shut down entirely dark, except on one side, where an open space is seen apparently a few feet wide, the cloud being there, as here, from one to three miles high.

"Thunder storms," says a popular writer, "are usually attended by a change in the direction of the wind, which accounts for the condensation of atmospheric vapor; indeed, one of the most sublime elements of a storm of this nature is the conflict and raging of opposing currents."

In the Meteorological Register of Yale College are recorded one hundred and sixteen thunder storms which occurred between 1804 and 1823. Of this number ninety-nine were either preceded or followed by an alteration in the direction of the wind, the change, in fifty instances, being from a south-westerly to a north-easterly breeze.

Since the air abounds with vapor when its temperature is high, the condensation will be most copious if loss of heat then suddenly take place. We, therefore, easily perceive the reason why thunder storms are more frequent in Summer than in Winter, in low than in high latitudes, and their intensity greater in the tropical climes. For the same reason, they happen more frequently after mid-day than in the morning.

LIGHTNING.

Lightning has been divided by Arago into these three kinds, principally distinguished by their form, viz: zigzag lightning, sheet lightning, and ball lightning.

Zigzag lightning. — This appears as a narrow jagged line of intensely vivid light, traversing space with extreme velocity.

Sheet lightning. — This kind is most common, and appears during a storm as a diffuse glow of light illuminating the edges of the clouds, and at times breaking out from the central mass.

Ball lightning. — Philosophers have not yet been enabled to account for lightning of this description. It has, however, been supposed to arise from an uninterrmitted discharge of electricity.

Heat lightning. — It not unfrequently happens during the severe evenings of Summer that the horizon is illuminated for many hours with successive flashes of light, unattended with thunder. This is called heat lightning, and has much perplexed meteorologists. It is affirmed by some that this illumination is the reflection from the atmosphere, as the lightning of remote storms themselves being so far distant that their thunders cannot be heard."

MOON AND WEATHER.

Mr. Merriam, who, probably, watched the weather and made more close and accurate observations with instruments for over thirty years than any man living, declares that in all his experience he has never been able to perceive that the moon has the least influence upon the weather; and yet, what multitudes are converts to this rank heresy! They run to the almanac when the moon is new, when it quarters, when it is full, and predict a change in the weather at these points. The fact is, the moon is new, or quarters, or is full, once a week the year round, while in our climate the weather is subject to constant changes, sometimes once a week, at other times, little change for weeks together; but still, if a change in the weather takes place anywhere near the change in the moon, she is the author of the change.

Some people seeing a new moon call it a wet or dry moon, from the form it presents. The new moon in June runs highest in the whole year, while that in December runs lowest, and hence, those positions. When the moon after the change runs high, the sun being north shines on on ☽ the north side: this is called a wet moon; and when she runs low after the change, ☾ a dry one. This is the whole of this fallacy.

THEORIES.

WEATHER,—the state or condition of the atmosphere with respect to heat, cold, dryness, moisture, wind, rain, snow, fogs, &c. The application of the various causes which determine the state of the atmosphere, and produce those changes which are incessantly taking place in its condition, and which are popularly called the *weather*, forms the subjects of *Meteorology* and *Climate*.

"In all ages of the world mankind have attempted to explain and prognosticate the changes of the weather; but such is the complication of the subject, and the vast multitude of circumstances to be taken account of, that no theory can furnish rules for determining the order in which they succeed each other, or for predicting the state of the weather at a future time, with any approach to certainty. Nevertheless, all the different modifications of the atmosphere, and the necessary results of principles, not only fixed and unalterable in their nature, but (many of them, at least) well known in their separate and individual operation. The difficulty of tracing the results of their combined influences arises chiefly from their complexity and endless concatenation.

"The principal cause of all the variations which take place in the state of the atmosphere is the heating action of the sun's rays: but, in order to appreciate correctly its effect, it is necessay to know not only the extent of the atmosphere, but the properties of all the substances of which it is composed. Modern science has discovered that the atmosphere is composed of three different gaseous fluids, everywhere combined in the same proportions, and penetrated by an ever varying quantity of elastic vapour. These two distinct envelopes of air and vapor

mechanically mixed have different relations to heat; and, therefore, in consequence of the unequal temperature of the surface of the earth, with which they are in contact, they cannot both be in a state of equilibrium at the same time. In consequence of the diurnal rotation, the different parts of the atmosphere are constantly receiving different quantities of heat, as the solar rays penetrate more or less obliquely. This inequality of temperature produces winds, which, if the surface of the earth were perfectly regular and homogeneous, would always blow in the same direction; but the surface of the earth being composed of materials of various kinds, and irregularly disposed, the distribution of heat over it is extremely irregular. The winds, sweeping along the surface, acquire its temperature; and hence, the atmosphere also becomes irregularly heated. This produces an accumulation of air at one place, and a deficiency at another; and hence, a subsequent rush to restore the equilibrium. As the air is cooled it becomes also incapable of holding the same quantity of aqueous vapour, a portion of which is therefore set free, and gives rise to clouds, mist, rain, dew, snow, &c. Besides all this, there is to be taken into account the development of electricity; the influences of light and galvanism; the agitation of the atmosphere produced by the rise and fall of the tides; and, probably, a variety of other circumstances with which we are entirely unacquainted. This very imperfect enumeration may serve to give an idea of the difficulties to be overcome in forming a theory of the weather.

"It has always been a favorite prejudice that the weather is influenced, in some mysterious manner, by the moon. The moon can be supposed to act on the earth only in one of three ways, namely: by the light which it reflects, by its attraction, or by an emanation of some unknown kind.

Now the light of the moon does not amount to the one hundredth thousandth part of that of the sun; and the heat which it excites is so small as to be altogether inappreciable by the most delicate instruments, or the best devised experiments. No effect can be attributed, therefore, to the moon's light. With regard to the attraction of the moon, we see its influence on the tides of the ocean, and might, therefore, be disposed to allow it a similar influence on the atmosphere; but when we take into account the small specific gravity of atmospheric air in comparison with water, and the consequent smallness of the mass of matter to be acted upon, it will readily be perceived that this influence, also, must be extremely feeble. In fact, it has been demonstrated by Laplace that the joint action of the solar and lunar attraction is incapable of producing more than an atmospheric tide flowing westward at the rate of about four miles a day, and, consequently, scarcely, if at all, appreciable. As to the remaining supposition that the moon may act on the atmosphere by some obscure emanation, it is sufficient to remark that no meteorological observations that have yet been made afford the slightest traces of any such connection between the earth and its satellite. The registers which are now kept in various observatories and other places also prove, contrary to the popular belief, that the changes of weather are in no way whatever dependent on the lunar phases."—*Brande's Encyclopædia of Science, Literature, and Art*: an English work, 1843.

The moon has been found to have a little heat which comes to the earth, but only a very little indeed.

WATER SPOUTS—WHIRLWINDS.

A WATER SPOUT is a whirlwind over an expanse of water, as the sea or a lake, differing from a land whirl in no other respect than that water is subjected to its action, instead of the bodies upon the surface of the earth.

DIMENSIONS.—The diameter of the spout at its base ranges from a few feet to several hundred, and its altitude is supposed by some to be at times as great as a mile. In the account given by the Hon. Captain Napier of a spout he beheld in 30 deg. 47 min. N. Lat. and 62 deg. 40 min. W. Lon., the diameter was judged to be three hundred feet; and the height of the column to the point where it entered the hanging cloud was computed, from observations taken by the quadrant, to be seventeen hundred and twenty feet, or nearly one-third of a mile.

POPULAR ERROR.—It is a common belief that water is drawn up by the action of the spout into the clouds; but there is no proof, whatever, of a continuous column within the whirling pillar, and the fact that the water which sometimes falls from a spout upon the deck of a vessel is always fresh, sufficiently refutes the idea. The torrents of rain, by which this phenomenon is often accompanied, can be fully accounted for by the rapid condensation of vapour that occurs when the warm, humid air of the sea flows inward to the vortex of the whirl, and there combines with the cold air of the upper regions of the atmosphere, which descends to fill the partial void. From this union the electric phenomena of water spouts arise, and the violent hail showers that at times prevail; the mode, however, in which they originate will be explained hereafter. When a vessel is in the vicinity of

water spouts, cannon shots are usually fired for the purpose of destroying them, lest the vessel should be injured if a spout were to pass over it. It is not improbable that such an effect may be produced when the spout is either struck by the balls or violently agitated by the concussion of the air arising from the discharges.

Sand Pillars.—Another form of the whirlwind is exhibited in the pillars of sand which are not unfrequently seen in the deserts of Africa and Peru. Bruce, on his journey to Abyssinia, beheld eleven vast columns of sand of lofty height moving over the plain at the same time; some with a slow and majestic motion, and others with great velocity. Now, with their summits reaching to the clouds, they rapidly approached the terrified observers, and, the next moment, were borne away by the wind with incredible swiftness. Their tops, at times, were seen separated from the main pillars, and the latter were often broken in two, as if struck by a cannon shot. The diameter of the largest was about ten feet. While Mr. Adinson was crossing the river Gambia, a sand whirl, twelve feet in breadth and two hundred and fifty in height, passed within forty yards of his boat.

The same phenomena are seen upon the Peruvian coast. "The sand," says Dr. Tschndi, "rises in columns from eighty to a hundred feet high, which whirl about in all directions, as if moved by magic. Sometimes they suddenly overshadow the traveller, who only escapes by rapid riding."

HEIGHT OF CLOUDS.

"The computation of many distinguished observers have been collected by Kaemtz, and from these it appears that clouds range in height from 1,300 to 21,320 feet.

"The extreme elevation here given is, however, not sufficiently great; for clouds are sometimes seen floating above the summit of Chimborazo, which rises 21,480 feet above the sea level; and when Gay Lussac, in the mouth of September, 1804, ascended in a balloon to the altitude of 23,000 feet, he beheld clouds still soaring above him apparently at a great height. Though thunder storms prevail on the lower regions of the atmosphere, they have often been seen at a very great altitude. A storm observed by Kaemtz, amid the mountains of Switzerland, rose to the height of more than 10,000 feet, and the dwellers in the vale of Chamouni assured him that storms frequently swept over the summit of Mount Blanc. On the peaks of the Cordilleras a violent thunder storm was encountered by Lacondamine and Bogner, at an elevation of even 16,000 feet.

"Vitrified rocks have, at times, been discovered at lofty heights; and as this change is supposed by some to have been effected by lightning, they have sought to determine the altitude of thunder storms from facts of this kind. The reasoning, however, is incondusive; for these vitrifications may be owing to other causes, and were we even to grant that they are produced by lightning, the case is, by no means, proved; since a flash sometimes passes between the clouds and the earth, when the former are below the point that is struck. Thus, on May 1st, 1800, a church, situated on Mount St. Ursula, a lofty peak in Styria, was struck; and seven persons were killed by a flash of lightning darting upwards from a thunder storm below."

HAIL.

The ice that descends in showers, and usually in summer, is called hail. It is different from sleet, which is nothing more than frozen rain, and occurs only in cold weather.

In May, 1847, hail stones of immense size descended near the town of McDonough, in Georgia; one of them was measured an hour after it fell, and found to be ten inches in circumference. During a terrific storm that occurred at Cazorta, in Spain, on June 13th, 1829, the roofs of the houses were broken in by the hail. Some of the stones are stated to have weighed nearly four and one half pounds.

OLMSTED'S THEORY.—Professor Olmsted, of Yale College, considers electricity as an affect, and not the cause of hail storms. According to his theory, which has been very extensively received, the cold body of air derives its low temperature, not from electricity, but from some known scource of cold; and the combination which occasions the hail may arise in various ways, the principal of which appears to be the following:

First. An exceedingly cold wind coming from a region far above the limit of perpetual frost may meet with a current of warm air blowing from a point many thousand feet below this limit.

Secondly. By the force of whirlwinds large volumes of warm air from the surface of the earth may be suddenly transported into the higher and colder regions of the atmosphere.

Thirdly. In the vicinity of lofty mountains cold blasts are frequently known to sweep down their sides from the snowy peaks and glaciers, and mingle with the warm atmosphere of the vales.
